Part 1: Schrödingers Equation and the Kronig-Penney Model

Problem 1

(a) Start from the general, time-dependent Schrödinger equation

$$i\hbar \frac{\partial \psi(x, t)}{\partial t} = -\frac{\hbar^2}{2m} \frac{\partial^2 \psi(x, t)}{\partial x^2} + V(x)\psi(x, t)$$

We assume that we can the solutions can be separated into spatial and time-dependent parts. Therefore we can assume that $\Psi(\mathbf{x}, t) = \psi(\mathbf{x})T(t)$, where $\psi(\mathbf{x})$ is the spatial part, and $T(t) = e^{(-\frac{iEt}{\hbar})}$ is the time-dependent part.

By replacing this in the Schrödinger equation

$$i\hbar \psi(\mathbf{x}) \frac{dT}{dt} = -\frac{\hbar^2}{2m} T(t) \nabla^2 \psi(\mathbf{x}) + V(\mathbf{x})\psi(\mathbf{x})T(t)$$

Divide both part with $\psi(\mathbf{x})T(t)$ to separate the variables:

$$i\hbar \frac{1}{T(t)} \frac{dT}{dt} = -\frac{\hbar^2}{2m} \frac{1}{\psi(\mathbf{x})} \nabla^2 \psi(\mathbf{x}) + V(\mathbf{x})$$

The right side of this equation only depend on spatial variables, while the left side are only dependent on time. Therefore both side must be constant to satisfy the equation for all \mathbf{x} and t . we call this constant for energy E , which gives us two equations:

$$i\hbar \frac{1}{T(t)} \frac{dT}{dt} = E$$

$$-\frac{\hbar^2}{2m} \frac{1}{\psi(\mathbf{x})} \nabla^2 \psi(\mathbf{x}) + V(\mathbf{x}) = E$$

After reorganising the other equation we get the time independent Schrödinger equation:

$$E\psi(\mathbf{x}) = -\frac{\hbar^2}{2m} \nabla^2 \psi(\mathbf{x}) + V(\mathbf{x})\psi(\mathbf{x})$$

b) Consider the infinite quantum well, described by the potential

$$V(x) = \begin{cases} \infty & x \leq 0 \\ 0 & 0 < x < L \\ \infty & x \geq L \end{cases}$$

This is a infinite quantum well in one dimension, therefore the particle can only move along the x-axis where $0 < x < L$. Since the potential is infinitely high outside the well, the wave function must be zero outside the well. Inside the well the wave function and its second derivative must be continuous. The wave equation only can exist inside the well, this implies that the wave equation is also normalizable.

In the area $0 < x < L$, the potential energy $V(x) = 0$, this gives us:

$$\frac{\partial^2}{\partial x^2} \phi = -\frac{2m}{\hbar^2} E \phi$$

We copy Faststoff project part one:

$$k^2 = \frac{2mE}{\hbar^2}$$

$$\frac{\partial^2}{\partial x^2} \phi = -k^2 \phi$$

The general solution must be:

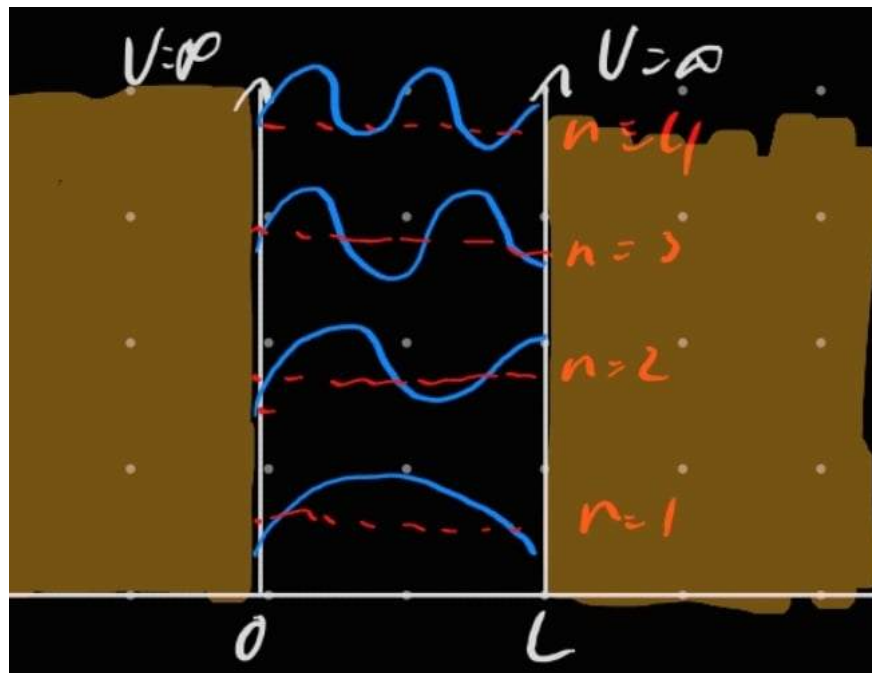

$$\phi(x) = A \sin(kx) + B \cos(kx)$$

For the function to be normalizable B must equal to 0. This does also imply that $\phi(L) = A \sin(kL) = 0$

This gives us the equation

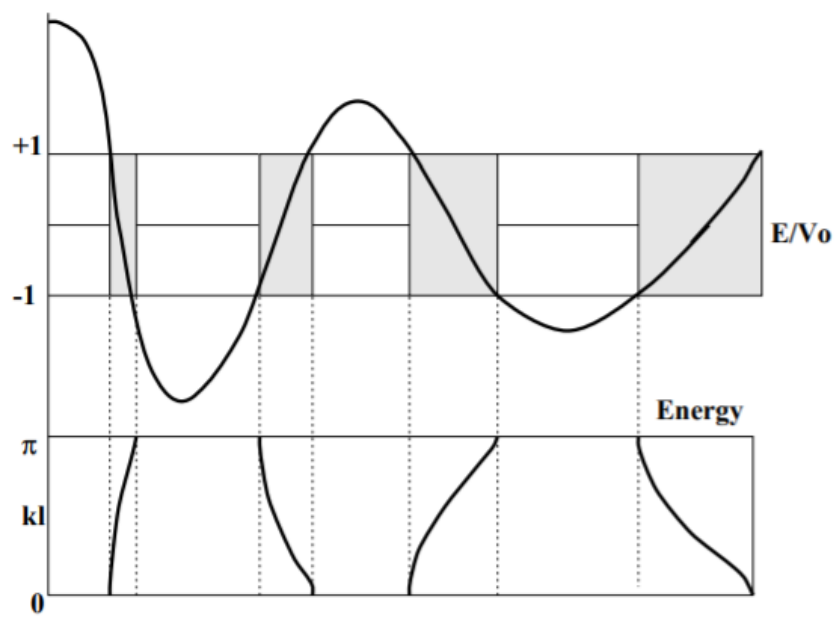

$$\phi(x) = \sqrt{\frac{2}{L}} \sin\left(\frac{n\pi x}{L}\right)$$

where the integral over the function from 0 to $L = 1$

(c) Kronig-Penney Model

By solving the Kronig-Penney model, we can calculate the dispersion relation by finding the energy levels for different values of the wavevector k . This gives us a function $E(k)$ that describes how the energy of an electron changes with the wave equation mentioned in the previous problem.

Part 2: Effective Mass

Problem 2

I expect to find the electrons with the highest mobility in the conduction band minima Γ as it has the highest curvature. This will give us the least effective mass as

$$m^* = \hbar^2 \frac{\partial^2 E(k)}{\partial k^2}$$

Problem 3

You cannot find information about the effective mass as the effective mass are affected by the medium in which the electron it is traveling thru as well as the direction of the velocity in the medium as well.

Part 3: Carrier Concentrations

Problem 4

a) State the fermi-dirac distribution and explain what it describes.

The fermi-dirac distribution describes the probability for if a given energy state is occupied by a electron at a given temperature. It is given by the equation:

$$f(E) = \frac{1}{e^{\frac{E-E_F}{k_B T}} + 1}$$

Where $f(E)$ is the probability for if a given energy state with the energy E is occupied by a electron. E_F is the Fermi-energy, k_B is Boltzmanns constant, and T is the temperature.

b) The general expression for calculating the concentration of electrons in the conduction band is

$$n_0 = \int_{E_c}^{\infty} f(E)N(E)dE$$

Explain the terms and parameters in the equation above and use it to derive the simplified expression
